ABSTRACT. Voltage controlled oscillators are present in the most of the digital communication system. In our days, they are used to control the phase in microwave antenna arrays. In our days, they are used to control the phase in microwave antenna arrays. In our days, they are used to control the phase in microwave antenna arrays. Researchers made so that a particular phase shift can be obtained by choosing the free-running frequencies of the oscillators in the array. In this paper, we have analyzed, in different ways, the array of coupled Van der Pol oscillators, in the array. The phase shift between output voltages of each oscillator. Because the coupling circuit is a two-port passive complex network, a new software which can generate in full-symbolic or numeric-symbolic form the Y, Z, H, and fundamental parameters of a two-port structure was implemented. Our procedure can also determine all the resonant frequencies of any two-port configuration as functions of the two-port circuit parameters. The procedure is based on the modified nodal equations in full-symbolic form and/or on the state equations in full-symbolic normal form, in the frequency domain. For this procedure a new program called ANCSYANP (Analog Circuit Symbolic Analysis Program) was elaborated. Some illustrative examples are done.

Keywords: symbolic analysis, phase shift, synchronization frequency, Van der Poll oscillator, Y parameters, time analysis, frequency analysis.

1. INTRODUCTION

Voltage controlled oscillators are important components in the most digital communication system. Recently microwave oscillators are used to control the phase in microwave antenna arrays. Beam steering methods. A voltage controlled oscillator (VCO) is a circuit that produces an oscillatory output [1 - 8, 11, 12]. The frequency of the output signal depends on the level of an input voltage signal supplied to the VCO. The range of the frequency is chosen according to our purpose, but mainly VCO’s produce high frequency signals.

The radiation pattern of a phased antenna array is steered in a particular direction by controlling the phase gradient existing between the signals applied to adjacent elements of the array. The required phase shift between output voltages of each oscillator can be obtained by detuning the free-running frequencies of the outermost oscillators in the array [2, 3]. Furthermore, in [4-8] it is shown that the resulting inter-stage phase shift does not dependent on the number of oscillators in the array.

The aim of this paper is to present the symbolic analysis of the array of coupled Van der Pol oscillators, considering the coupling circuit as a passive two-port circuit. Therefore, a new software which can generate in full-symbolic or numeric-symbolic form the Y, Z, H, and fundamental parameters of any two-port structure was developed. The procedure is based on the modified nodal equations in full-symbolic form and/or on the state equations in full-symbolic normal form, in the frequency domain.

Because, in sinusoidal behaviour the two voltage-controlled nonlinear resistors of each pair of two coupled Van der Pol oscillator can be substituted by two linear resistors having negative resistances. In this case the oscillator circuit can be analyzed by the complex representation method [3, 6 - 10].

The active parts of the two Van der Pol oscillators are modeled by two voltage-controlled nonlinear resistors (see Fig. 1), [3, 6, 7]. The nonlinear characteristics of the two voltage-controlled nonlinear resistors are expressed as it follows:

\[ i_{n1} = -av_1^3, \quad i_{n2} = -av_2^3, \]  

(1)

where \(a\) is the negative conductance necessary to start the oscillation and \(b\) a parameter used to model the saturation phenomenon.

Assuming the voltages have sinusoidal oscillation so that \(v(t) = A \cos(\omega t)\), the expressions of the currents through the two nonlinear resistors can be written as:
\[ i(t) = \left( -a + \frac{3}{4} b A_1^2 \right) A \cos(\omega_0 t) + b A_2^3 \cos(3\omega_0 t). \]  

(2)

Therefore, in the sinusoidal behavior (neglecting the third harmonic) the two nonlinear resistors can be modeled by two linear resistors with the conductances:

\[ G_{01} = -a + \frac{3b}{4} A_1^2; \quad G_{02} = -a + \frac{3b}{4} A_2^2, \]  

(3)

where \( A_1 \) and \( A_2 \) are magnitudes of voltages \( v_1 \) and \( v_2 \).

In this paper, we have analyzed, in different ways, in time and also in frequency domain, the phase shift between output voltages of each oscillator.

The paper is organized as follows: a system of two Van der Pol oscillators coupled through a RLC circuit is presented in section II. In section III, the symbolic generation of the coupling circuit parameters with the new software is described followed by conclusions.

2. TWO COUPLED VAN DER POL OSCILLATORS THROUGH A SERIES RLC NETWORK

The base of this analysis is represented by VCO’s that have different free-running frequencies and are able to lock at a common frequency thanks to coupling circuits, [1, 2, 4, 8]. Two oscillators coupled through a resonant network can be synchronized at the same frequency. But the synchronization is highly dependent on the coupling network, [1 - 8, 11, 12, 14]. Coupled microwave oscillators have been modeled as simple Van der Pol oscillators [3, 6, 7]. This model provides satisfactory results for many applications. Also the simplicity of the equations is very helpful.

Figure 1 represents two oscillators coupled through a series RLC network. These oscillators are considered identical, except for their free-running frequencies. Thus, this work aims to determine values for these frequencies and for that of the coupling circuit that result in frequency locking.

The resonant frequencies for the two oscillators are:

\[ f_{01} = \frac{1}{2\pi\sqrt{L_1C_1}} = 950 \text{MHz}; \quad f_{02} = \frac{1}{2\pi\sqrt{L_2C_2}} = 1000 \text{MHz}. \]  

(4)

Resonant frequency of the RLC coupling circuit is:

\[ f_c = \frac{1}{2\pi\sqrt{L_c C_c}} = 972 \text{MHz}. \]  

(5)

In figure 2 the waveforms for the output voltages corresponding to the two oscillators are shown and in figure 3 the Fourier characteristic of the two waveforms is presented.

Performing Spice simulation (or Matlab simulation based the state equations, [9, 10, 13, 14]) we get the magnitudes values \( A_1 = 3.67 \text{ V}, \quad A_2 = 3.6557 \text{ V} \) (Fig. 2), and the synchronization frequency \( f_s = 982.196 \text{ MHz} \) for the initial conditions \( v_{c1}(0) = 2.0 \text{ V} \) and \( v_{c2}(0) = 1.0 \text{ V} \) (Fig. 3). According to the assumptions presented in Section I, in sinusoidal behaviour the two voltage-controlled nonlinear resistors can be substituted by two linear resistors having the expressions (3). In this case, the circuit in Fig. 1 can be analyzed by the complex representation method [9, 10].
AN ANALYTIC METHOD FOR TWO-PORT PASSIVE NETWORK
COMPUTING FOR ANALYSIS OF COUPLED OSCILLATORS

The complex admittances, in the sinusoidal behaviour, corresponding to two oscillators and to coupled RLC circuit have the following expression:

\[ Y_1 = j\omega C_1 - a + \frac{3b}{4} A_1^2 + \frac{1}{j\omega L_1} + \frac{1}{R_1}; \]
\[ Y_2 = j\omega C_2 - a + \frac{3b}{4} A_2^2 + \frac{1}{j\omega L_2} + \frac{1}{R_2}; \]
\[ Y_c = \frac{\omega^2 C_c}{R C_c (\omega + \sqrt{j C L \omega^2 - 1})}. \]

For the circuit in Fig. 1 the equations in complex form, when the two voltage-controlled nonlinear resistors are substituted by two linear resistors according to (3), can be written as:

\[ Y_1 V_1 = -Y_1 V_1 + Y_2 V_2 \]
\[ Y_2 V_2 = Y_1 V_1 - Y_2 V_2. \]

If we denote \( X = \frac{V_1}{V_2} = \frac{A_1}{A_2} e^{j\phi_{X}} \) and take the numeric values of the circuit parameters from Fig. 1, and \( a = 0.0085, b = 0.00071 \), then (7) becomes a system of two equations with two unknowns, \( X \) and \( \omega \). Solving these algebraic equations, we obtained the following results:

\[ \frac{V_{o1}}{V_{o2}} = \frac{X_{c-analytic}}{0.8786 + 0.4674 j} \Rightarrow \phi_{21-analytic} = \alpha_{o1} - \alpha_{o2} = \arg \left( \frac{V_{o1}}{V_{o2}} \right) = -28.028^\circ \]
\[ V_{o1}/V_{o2} = 0.995 \]
\[ \omega_{c-analytic} = 0.6178 \times 10^{10} \text{ rad/s}. \]

In order to compute the phase shift, using Spice or Matlab simulation, we can use the following relation:

\[ \varphi_{21-\text{Spice}} = f_s \cdot \left( t_{o1-m} - t_{o2-m} \right) \times 360, \]

where \( f_s \) - is synchronisation frequency (see Fig. 3) and \( t_{o1,m} \) (\( t_{o2,m} \) ) - represents the time moment when the first (second) oscillator voltage is maximum (see Fig. 2). Replacing the numeric values, the result is:

\[ \varphi_{21-\text{Spice}} = -27.226^\circ. \]

Taking into account the amplitudes of the output voltages, the ratio of these amplitudes has the value:

\[ \frac{V_{o1m}}{V_{o2m}} = \frac{3.7}{3.6557} = 1.0121. \]

We can remark the good agreement between the results obtained by Spice simulation and by our procedure.

R. York proves in [1, 5, 8] that the ability of two oscillators to lock to a common frequency is affected by the following parameters:

\[ \lambda_0 = \frac{1}{G_0 R_c} \] - the coupling constant, with \( G_0 \) being the first-order term of the Van Der Pol nonlinear conductance;
\[ \omega_a = \frac{G_0}{2 \cdot C_i} \] - is the bandwidth of the oscillator \( i \);
\[ \omega_{ac} = \frac{G_0}{2 \cdot C_c} \] - represents the bandwidth of the coupling circuit;
\[ \omega_c = \frac{R_c}{2 \cdot L_c} \] - is the bandwidth of the unloaded coupling circuit.

In the following, the oscillators free-running frequencies \( \omega_{01} \) and \( \omega_{02} \), and the synchronization frequency of the system \( \omega_s \), are referred to the frequency of the coupling circuit, of the oscillators, \( \omega_{0c} \), using the substitutions below:

\[ \Delta \omega_{01} = \omega_{01} - \omega_{0c}, \quad \Delta \omega_{02} = \omega_{02} - \omega_{0c}, \quad \Delta \omega_s = \omega_s - \omega_{0c}. \]

The formula proposed by R. York, [1, 5, 8], to compute the phase shift between the two oscillators has the following expression:

\[ \varphi_{21-\text{York}} = \arctan \left( \frac{\Delta \omega_{02}}{\omega_a \left( \omega_{02} - \omega_{0c} \right) - \lambda_0^2 - \lambda_0 \Delta \omega_{02} + \lambda_0 \Delta \omega_{0c}^2} \right) \]

where \( A_2 \) is the magnitude of the output voltage corresponding to the second oscillator.

Using the numeric values of the circuit parameters corresponding to the circuit in figure 1, the result is:

\[ \varphi_{21-\text{York}} = -27.357^\circ \]

The value of shift phase obtained by York’s procedure is very close to the values given by the above two techniques, the errors being very small.

\[ \varepsilon_X = -1.668 \text{ [\%]} \]
\[ \varepsilon_{\omega_{\text{omega}}} = 0.163 \text{ [\%]} \]
\[ \varepsilon_{\varphi_{21-\text{York}}} = 2.945 \text{ [\%]} \]
\[ \varepsilon_{\varphi_{21-\text{analytic}}} = 0.48 \text{ [\%]} \]

3. TWO COUPLED VAN DER POL OSCILLATORS THROUGH A TWO-PORT PASSIVE NETWORK

We consider the circuit represented in Fig. 4. In this case the coupling circuit is a two-port passive network.
Performing Spice simulation (or Matlab simulation based the state equations, [10, 11]) we get the magnitudes values $A_1 = 3.1891V$, $A_2 = 3.69$, and the synchronization frequency $f_s = 908.247MHz$ for the initial conditions $v_1(0) = 2.0 V$ and $v_2(0) = 1.0 V$, as it shown in Fig.5 and in Fig. 6.

According to the assumptions presented in Section I, in sinusoidal behaviour the two voltage-controlled nonlinear resistors from Fig. 4 can be substituted by two linear resistors having the expressions (3). Thus, the circuit in Fig. 4 can be analyzed by the complex representation method [9, 10].

In order to automatically generate (in symbolic or numeric-symbolic form) the $Y$ parameters of this circuit we use the ANCSYANP, [10].

Because the coupling network in Fig. 4 is a two-port passive circuit, in order to generate $Y$ parameters this circuit we use the ANCSYANP, [10].

In order to generate the $Y$ parameters by using the ANCSYANP program we take into account the circuit parameters associated to the passive two-port which model the coupling circuit, we adapted the general software - ANCSYANP (Analog Circuit Symbolic Analysis Program) [10]. The new analysis tool based on the modified nodal analysis (MNA) generates, starting from the circuit net list, the $Y$, $Z$, $H$ and fundamental parameters, for any linear and/or nonlinear time-invariant two-port analog circuit, in symbolic form. It is an interactive tool that combines symbolic and numeric computational techniques, and which uses the facilities of the symbolic simulator Maple to manipulate the symbolic expressions.

Running ANCSYANP all transfer admittances in full symbolic form are obtained. The expressions of these transfer admittances have the following structure:

$$Y_{11} := \frac{\omega^*}{-\omega^* \cdot C_{ced}^* \cdot L_c^* \cdot C_{ced} \cdot L_c^* \cdot C_{ced} \cdot C_{ced}^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^*}$$

$$Y_{12} := \frac{\omega^*}{-\omega^* \cdot C_{ced}^* \cdot L_c^* \cdot C_{ced} \cdot L_c^* \cdot C_{ced} \cdot C_{ced}^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^*}$$

$$Y_{21} := \frac{\omega^*}{-\omega^* \cdot C_{ced}^* \cdot L_c^* \cdot C_{ced} \cdot L_c^* \cdot C_{ced} \cdot C_{ced}^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^*}$$

$$Y_{22} := \frac{\omega^*}{-\omega^* \cdot C_{ced}^* \cdot L_c^* \cdot C_{ced} \cdot L_c^* \cdot C_{ced} \cdot C_{ced}^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^* + (C_{ced} \cdot R_c + C_{ced} \cdot R_c)^* \cdot \omega^*}$$

Fig. 4. Two parallel resonant circuits coupled through a two-port passive network.

Fig. 5. Waveforms present at the output of each oscillator in the case of two oscillator array from Fig. 4, $v_{c1} = V(1)$ – blue and $v_{c2} = V(4)$ - red.

Fig. 6. Synchronization frequency obtained by a Fourier analysis.

Fig. 7. The equivalent circuit scheme for the computing of the $Y$ parameters.
AN ANALYTIC METHOD FOR TWO-PORT PASSIVE NETWORK COMPUTING FOR ANALYSIS OF COUPLED OSCILLATORS

\[ L_0 = C_e \cdot L_e \cdot \omega^2 + (C_{oel} \cdot R_c + C_e \cdot R_e) \cdot \omega \cdot j \]
\[ Y_{22} = \omega \cdot (C_{oel} \cdot R_c + C_{oel} \cdot R_e + C_e \cdot R_e + C_{oel} \cdot R_{oel}) \]
\[ C_{oel} \cdot R_e \cdot \omega \cdot j + (C_{oel} \cdot R_e + C_{oel} \cdot R_e + C_e \cdot R_e + C_{oel} \cdot R_{oel}) \]
\[ L_0 \cdot C_{oel} \cdot R_c + C_{oel} \cdot L_e \cdot C_e \cdot R_e + C_e \cdot R_e + C_{oel} \cdot L_e \]
\[ y_{= 2} \cdot y_{= 2}^* = \omega \cdot (C_{oel} \cdot L_e \cdot C_e \cdot L_e) \cdot \omega \cdot j + (C_{oel} \cdot R_c + C_e \cdot R_e \cdot \omega \cdot j) \]

The resonant frequencies corresponding to the transfer admittances (15) have the following values:
\[
\begin{align*}
&f_{\text{rez}_Y11} := \{0.9699 \times 10^9, 0.1142 \times 10^9\} \\
&f_{\text{rez}_Y12} := \{0.9699 \times 10^9\} \\
&f_{\text{rez}_Y21} := \{0.9699 \times 10^9\} \\
&f_{\text{rez}_Y22} := \{0.1137 \times 10^9\}
\end{align*}
\] (16)

The resonant frequencies of the transfer admittances (15) have the values near to the value of the synchronization frequency.

For the circuit in Fig. 4 the equations in complex form, when the two voltage-controlled nonlinear resistors are substituted by two linear resistors according to (3), can be written as:
\[
\begin{align*}
\frac{Y_1}{V_1} &= -\frac{Y_{11}}{V_1} - \frac{Y_{12}}{V_2} \\
\frac{Y_2}{V_2} &= -\frac{Y_{21}}{V_1} - \frac{Y_{22}}{V_2},
\end{align*}
\] (17)

where: \( Y_1 \) and \( Y_2 \) are the complex admittances corresponding to the two oscillators, having the expressions (6) and \( Y_{11}, Y_{12}, Y_{21}, Y_{22} \) are the complex transfer admittances corresponding to the coupling circuit between the two oscillators in Fig. 4, given by the relations (15).

If we denote \( X = \frac{V_1}{V_2}, \frac{A_1}{A_2} = e^{j\varphi}\) and take the numeric values of the circuit parameters from Fig. 4, and \( a = 0.009, b = 0.0007, A_1 = 3.2732 \text{ V}, \) and \( A_2 = 3.7286 \text{ V}, \) then (4) becomes a system of two equations with two unknowns, \( X \) and \( \varphi. \)

The results obtained by solving the equations (17) and by Spice or Matlab simulation (see relation (9)) have the following structure:
\[
\begin{align*}
X_{\text{analytic}} &= 0.6379 + 0.6029 j; \\
X_{\text{analytic}} &= 0.8777; X_{\text{Spice}} = 0.8784 \\
\omega_{\text{analytic}} &= 57.0 \cdot 10^8 \text{ rad/s}; \\
\omega_{\text{Spice}} &= 56.78 \cdot 10^8 \text{ rad/s}; \\
\varphi_{21,\text{analytic}} &= 43.4^\circ; \varphi_{21,\text{Spice}} = 44.92^\circ; \\
f_{s,\text{Spice}} &= 0.904127 \text{ GHz.}
\end{align*}
\] (18)

We denote that the results obtained by the two procedures are very closed.

4. CONCLUSIONS

The way how oscillators work and the phase shift are very important in orienting the radiation pattern, in a phased antenna array, in a certain direction. Researches are made so that a particular phase shift can be obtained by choosing the free-running frequencies of the oscillators in the array. In this paper different types of analysis were applied in order to compare the results obtained and also, for a better understanding of the influence the parameters have in the oscillators’ synchronization. The main limit we encounter is that the analysis is made around the synchronization frequency. Thus, there is a risk of malfunction outside this region.

Using suitable software we performed the symbolic analysis of an antenna array in order to compute in symbolic form the coupling circuit parameters. The existing software was enhanced with dedicated routines for generating the \( Y \) (admittance), \( Z \) (impedance), \( H \) (hybrid parameters) and fundamental parameters of the coupling networks, which are modeled by passive linear two-port circuits.

The results obtained by Spice simulation or by Matlab simulation (based on the state equations) are very closed to the ones obtained by frequency analysis (complex analysis) when the two voltage-controlled nonlinear resistors are modeled by two linear resistors having the conductances as the relations (3).

The symbolic expressions of the coupling circuit parameters are useful in writing the dynamic equations of an array of coupled oscillators for the automatic design of these devices.
